

# Taming the Wild: A Unified Analysis of HOGWILD!-Style Algorithms

Christopher De Sa, Ce Zhang, Kunle Olukotun, and Chris Ré cdesa@stanford.edu, czhang@cs.stanford.edu, kunle@stanford.edu, chrismre@cs.stanford.edu Departments of Electrical Engineering and Computer Science, Stanford University

# Overview

### **Everyone uses stochastic gradient descent!**

- ▷ De facto method for training models in machine learning.
- ▷ Important to run it fast on increasingly-parallel machines.

### **Common** heuristic: asynchronous HOGWILD! execution

- ▷ Run multiple threads of SGD in parallel without locks.
- ▷ Scales very well on modern hardware.
- often almost linearly
- ▷ Very widely used.

## Wide variety of applications and variants:

- ▷ PageRank approximations (FrogWild!)
- ▷ Deep learning (Dogwild!, DeepDive)
- ▷ Asynchronous stochastic coordinate descent (AsySCD)
- ▷ Asynchronous stochastic proximal iteration (APPROX)

## But it's hard to tell when a HOGWILD! algorithm will work.

▷ Can analyze each extension from scratch, but is cumbersome.

### **Our contribution: a unified analysis of HOGWILD!**

- ▷ Introduce a new *martingale-based* result that handles each variant as a different form of noise within a unified model.
- ▷ *Relax sparsity constraints* of previous convex results.
- ▷ Derive *first* HOGWILD! *convergence results for a nonconvex problem*, matrix completion.

# **Beyond HOGWILD!: Low Precision**

We propose BUCKWILD!, a fast heuristic for asynchronous SGD using low-precision arithmetic.

▷ Low-precision lowers the required memory bandwidth. ▷ Also lets us use high-throughput SIMD instructions.

# Martingales and Stochastic Gradient Descent

### **Problem setup.**

We're trying to solve stochastic optimization problems of the form

minimize  $\mathbf{E}[\tilde{f}(x)]$  over  $x \in \mathbb{R}^n$ 

by repeatedly running *SGD updates* 

$$x_{t+1} = x_t$$

where  $G_t$  is a random *sample* from some distribution. The goal of the algorithm is to produce, by some time T, a sample in some success region S close to the optimum; if we don't, we say the algorithm has *failed*.

# **Convergence Rates for Asynchronous SGD**

## Modeling the hardware.

- depend on the hardware
- ditions
- machine:
- number of cores
- cache coherence protocol
- T1 updates part of model

# **Example Analysis: Convex Case**

Constructing this rate supermartingale follows from classic analysis of strongly-convex functions, and re-

### Martingales: The sequential case.

 $-\tilde{G}_t(x_t),$ 

A martingale-based proof for SGD starts with a rate super*martingale*, which is a function  $W_t : \mathbb{R}^{n \times t} \to \mathbb{R}$  that satisfies the following conditions. First,

 $\mathbf{E}\left[W_{t+1}(x_t - \nabla \tilde{G}_t(x_t), x_t, \dots, x_0)\right] \le W_t(x_t, x_{t-1}, \dots, x_0).$ 

Second, if the algorithm hasn't succeeded yet, then

 $W_t(x_t, x_{t-1}, \ldots, x_0) \ge t.$ 

A rate supermartingale immediately lets us bound the probability of failure of sequential SGD:

 $P(\text{sequential SGD doesn't succeed before } T) \leq \frac{\mathbf{E}[W_0(x_0)]}{T}.$ 

▷ Behavior of HOGWILD! SGD will

- hardware affects rate of race con-

 $\triangleright$  We use a parameter  $\tau$  to abstract away unnecessary details about the

 $\triangleright$  Roughly  $\tau$  is the number of writes that can be "in flight" at a time.

stant L, and that  $\mathbf{E}[\|\tilde{f}(x)\|^2] \leq M^2$ . Let  $S = \{x | \|x - x\|$  $x^* \parallel^2 \leq \epsilon$ . A *rate supermartingale* for this problem is

$$\frac{\epsilon}{\alpha^2 M^2} \log\left(e \left\|x_t - x^*\right\|^2 \epsilon^{-1}\right) + t$$

Main Theorem: HOGWILD! Convergence

Assume some regularity conditions on the rate supermartingale. First, W must be Lipschitz continuous:

 $||W_t(u, x_{t-1}, \dots, x_0) - W_t(v, x_{t-1}, \dots, x_0)|| \le H ||u - v||.$ 

Second,  $\tilde{G}$  must also be Lipschitz continuous:

$$\mathbf{E}\left[\left\|\tilde{G}(u) - \tilde{G}(v)\right\|\right] \le R \left\|u - v\right\|_{1}.$$

Third, the expected magnitude of an update must be bounded:

 $\mathbf{E}\left[\left\|\tilde{G}(x)\right\|\right] \leq \xi.$ 

Then the probability of failure is bounded by

 $P(\text{HOGWILD! doesn't succeed before } T) \leq \frac{\mathbf{E}[W(0, x_0)]}{(1 - HR\xi\tau)T}.$ 

**Convex case.** Assume that f is strongly convex with quires *no additional work beyond proving sequential* parameter c, that  $\nabla \tilde{f}$  is Lipschitz continuous with con- convergence. If we choose step size

$$\alpha = \frac{c\epsilon\vartheta}{M^2 + 2LM\tau\sqrt{\epsilon}}.$$

*t*. we can *bound* **HOGWILD**!'s probability of failure:

$$P(\text{fail}) \le \frac{M^2 + 2LM\tau\sqrt{\epsilon}}{c^2\epsilon\vartheta T} \log\left(e \|x_0 - x^*\|^2\epsilon^{-1}\right).$$

$$3 \\ 2 \\ 1 \\ 0 \\ -1 \\ -2$$

# **Non-Convex Case**

Our analysis is general enough to apply to a non-convex problem.

### Matrix completion

- ⊳ Non-convex because of unstable fixed points.
- ▷ Non-convexity means that standard convex analysis of HOGWILD! doesn't apply.
- ▷ No existing HOGWILD! results.

Because there was an existing martingale-based result for the sequential case, our method easily extends it to show that HOG-WILD! works for this problem.

This is backed up by experiments. Here we compare some trajectories of 12-thread HOGWILD! and sequential SGD on matrix completion — notice that the *dynamics are basically the same*.

# **Low-Precision with BUCKWILD!**

We ran BUCKWILD!, i.e. *low-precision asynchronous SGD*, on logistic regression. This table shows the training loss as precision is changed — notice that *low-precision has no effect on loss*.

ataset	Rows	Columns	Size	32-bit float	16-bit int	8-bit int
uters	8K	18K	1.2GB	0.5700	0.5700	0.5709
orest	581K	54	0.2GB	0.6463	0.6463	0.6447
CV1	781K	47K	0.9GB	0.1888	0.1888	0.1879
<i>Ausic</i>	515K	91	0.7GB	0.8785	0.8785	0.8781
						1

For convex functions with precision  $\kappa$ , our technique gets us

$$P(\text{fail}) \leq \frac{M^2(1+\kappa^2) + LM\tau(2+\kappa^2)\sqrt{\epsilon}}{c^2\epsilon\vartheta T} \log\left(e \|x_0 - x^*\|^2\epsilon^{-1}\right).$$

Performance of BUCKWILD! for Logistic Regression

▷ Speedup of BUCKWILD! running on dense RCV1 dataset.

- ▷ Significant speedup from low precision.
- $\triangleright$  Up to 2.3× *as fast* as the best HOGWILD!
